Key Setting Note:

Low-light real estate demands a tripod regardless of the camera used. The A7IV's 33-megapixel sensor and excellent dynamic range are significant advantages—you can recover shadow detail and balance bright windows with darker interiors in post. At f/8–f/11, the slow shutter speeds required (often 1–10 seconds) make a tripod non-negotiable. Enable Long Exposure Noise Reduction to reduce hot pixels and sensor glow; this doubles the exposure time, so budget accordingly. For rooms with mixed lighting—dim tungsten fixtures plus a hint of daylight through a window—shoot in RAW and set Kelvin to around 3200–3800K to balance the sources. The A7IV's dynamic range gives you flexibility to fine-tune colour and exposure in post without sacrificing quality.

Inner Signal Note:

"The A7IV has no IBIS in low light? Actually, it does—but even the best IBIS cannot replace a tripod when the exposure runs for seconds. The room is not moving. The light is not changing. The only variable is your willingness to wait. The sensor will collect light for as long as the shutter stays open. Use the tripod. Let the exposure run. The machine will capture the detail. You will capture the patience."
